**Abstract.** One hundred thirty-nine taxa of lichens including two lichen parasites are reported from St. Matthew and St. Paul Islands in the Bering Sea. *Caloplaca lithophila* is new to Alaska. Wide-ranging arctic-alpine and boreal species dominate the lichens; a coastal element is moderately represented, while amphi-Beringian species form a minor element. In comparison with St. Paul Island, St. Matthew Island is richer in arctic-alpine species.

The most isolated Bering Sea island groups are St. Matthew Island, including Hall and Pinnacle Islands, and the Pribilof Islands, including St. Paul and St. George. The Pribilof Islands are located 400 km north of the Aleutian Chain; St. Matthew lies an additional 400 km north of St. Paul and 330 km south of St. Lawrence Island; St. Matthew and St. Paul are 400 km from the Alaska mainland (Fig. 1). The isolation of St. Matthew and St. Paul Islands makes them of great phytogeographic interest. In spite of this, their lichen diversity has been poorly documented.

All of St. Matthew Island and the western coast of St. Paul Island are part of the Alaska Maritime National Wildlife Refuge managed by the U.S. Fish and Wildlife Service. St. Matthew is a Class I air quality area (Clean Air Act, 42 U.S. Code 7401 et seq.); the western coast of St. Paul Island is a Class II air quality area. In accordance with its responsibility for ensuring high air quality standards, the Service sought to assess the existing condition of wilderness resources of these islands in relation to air quality using the guidelines proposed by Fox et al. (1987). According to these procedures, the first step in characterizing the plant component is to establish a floristic list, which includes for each species distributional information. As the lichens of both islands were poorly known, a major objective of the present study was to list the lichens, including habitat and distribution information.

From a wildlife management perspective, lichens are important in the diet of caribou (Sjenneberg & Slagsvold 1979). A field study of reindeer-range re-

lationships was made on St. Matthew Island in 1953 (Klein 1959). This range study showed serious over-utilization of the lichens in the winter range by the introduced reindeer. A die-off of the herds occurred following over-utilization of the lichens and today the island is devoid of reindeer. Currently on St. Paul Island, a reindeer herd ranges throughout the island and uses lichens particularly in the winter. The herd has increased in numbers to about 600 and appears to be overgrazing lichens. Our list of the lichens provides basic information for an assessment of reindeer range and foraging ecology.

This paper reports lichens collected from the St. Matthew and St. Paul Islands, describes their habitats and phytogeographical distribution, and lists voucher collections. Hitherto the lichens have received moderate attention in these Bering Sea islands with St. Matthew being the least well known. References to the lichen taxa of St. Matthew Island are in Cummings (1910), Degelius (1937), Dibben (1980), Klein (1959), Rausch and Rausch (1968), Rothrock (1884), Thomson (1984, 1997), and Wetmore (1960), and for St. Paul Island in Arup (1994), Degelius (1937), Dibben (1980), Howe (1913), Llano (1950), Macoun (1899), Rothrock (1884), Schindler (1990), Thomson (1984, 1997), and Wetmore (1960), and possibly others that we may have overlooked. The nearest areas of relatively well-known lichen documentation are Adak Island (Talbot et al. 1997; 219 taxa), located in the central Aleutian Islands, and Izembek National Wildlife Refuge, located at the westernmost portion of the Alaska Peninsula (Talbot et al. 2000; 182 taxa), western Kodiak Island (Talbot 1998; 129 taxa), located in the Gulf of Alaska, and Tuxedni Wilderness Area (Talbot et al. 1992; 219 taxa) located in Lower Cook Inlet.

<sup>1</sup> Present Address: Alaska Biological Science Center, U.S. Geological Survey Biological Resources Division, 1011 East Tudor Road, Anchorage, Alaska 99503, U.S.A.

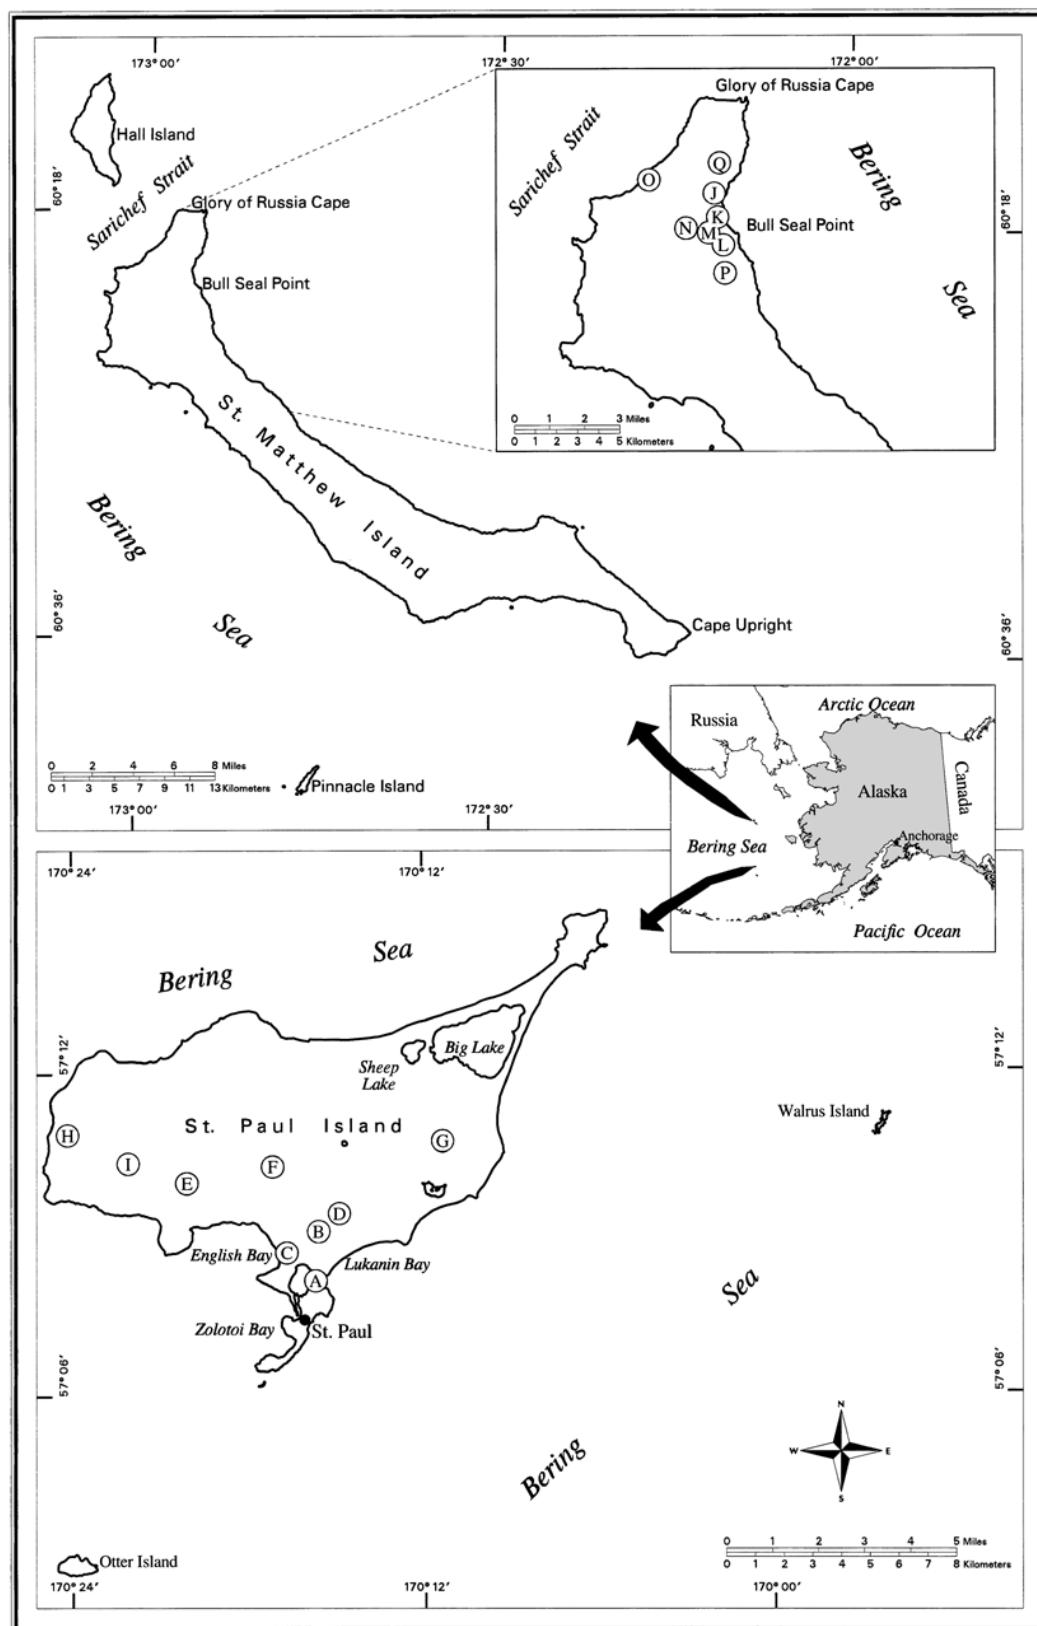

FIGURE 1. Location of St. Paul and St. Matthew Islands, Alaska, and map of the lichen collection sites. Circled letters are collection sites listed in the Methods section.

FIGURE 2. General aspect of the landscape of southwestern St. Paul Island, Alaska, in the Cone Hill area (Site I). Old volcanic cones rise approximately 100 m above the surrounding terrain. The island is mostly low-lying (<180 m) with no streams and nearly no wetlands. Common species collected in this area are *Cetraria ericetorum*, *Cladina mitis*, *Cladonia bellidiflora*, *C. gracilis*, *C. maxima*, *Melanelia hepaticola*, *Parmelia omphaloides*, *Peltigera malacea*, *Stereocaulon arenarium*, *S. intermedium*, and *Tuckermannopsis chlorophylla*.

#### STUDY AREA

St. Matthew and St. Paul Islands that comprise the study area occur in two distinctly different ecoregions of Alaska (Gallant et al. 1995). St. Matthew Island located at 60°30' N, 172°45' W occurs within the "Subarctic Coastal Plains" ecoregion, while St. Paul Island, located at 57°11' N, 170°18' W occurs within the "Aleutian Islands" ecoregion. In a floristic division of the Arctic, Yurtsev (1994) assigned St. Matthew Island to the Southern Hypoarctic tundra subzone, and St. Paul Island to the Oceanic Boreal subzone. St. Paul Island is relatively small (16 km across), mostly low-lying with no streams and a maximum elevation of 180 m (Bogoslof Hill) (Fig. 2). In contrast, St. Matthew Island is larger (56 km long, 6 km wide), more mountainous, rich in streams, and three mountains are in excess of 305 m; mountains at the northern end at the Glory of Russia Cape and the southern end at Cape Upright, rise to elevations of 450 m and 459 m, respectively (Fig. 3).

Vegetation of these Bering Sea islands was mapped as wet, moist, and alpine tundra (Selkregg 1974). Klein (1959) described the vegetation of St. Matthew Island. He classified the plant communities into five major groups based on landform and drainage characteristics: 1) "dry flats," dry tundra vegetation consisting mainly of lichens (*Cladina stellaris*, *Flavocetraria cucullata*, *Sphaerophorus globosus*, *Thamnolia vermicularis*), willows (*Salix*

*crassifolia* × *ovalifolia*), and sedges (*Carex nesophila*) that occur on well-drained rocky soils; 2) "dry, low ridge tops and benches," the vegetation is similar to the dry flats but lichen, willow, and moss cover is less and the well-drained mineral soils are exposed; 3) "moist, well-drained meadows," the vegetation of this type is closed and the mineral soils are exposed; the type is dominated by sedges (*Carex nesophila*), a diversity of alpine forbs (such as *Aconitum delphinifolium*, *Pedicularis capitata*, and *Valeriana capitata*), willows (*Salix rotundifolia*, *S. reticulata*), and lichens are very scattered; 4) "wet, poorly-drained meadows," the vegetation is dominated by wet sedge meadows (*Carex glareosa*, *C. stans*, *Eriophorum angustifolium*, *E. russeolum*) with *Sphagnum* spp., a few lichens (*Cladina stellaris*, *Thamnolia vermicularis*, and others), and vascular plants as *Petasites frigidus*, *Potentilla palustris*, *Rubus arcticus*, and *Salix fuscescens*; the type is common in some sections of flats, broad valleys, and low mountain passes with poorly drained soils; and 5) "rock rubble fields and high ridge cops," vegetation is mainly restricted to crustose lichens.

Macoun (1899: 560–561) described the vegetation of the Pribilof Islands as "tundra-like and much resembles the barren grounds of arctic America." He mentioned that common vascular plants of wind-exposed and elevated portions of the islands are *Arenaria macrocarpa*, *Artemisia globularia*, *Eritrichium chamissonis*, *Eutrema ed-*

FIGURE 3. General aspect of the fog-laden landscape of northeastern St. Matthew Island, Alaska, in the Bull Seal Point area (Sites L, M, and P); steep rock cliffs rise from the Bering Sea. St. Matthew Island is more mountainous and is richer in streams and wetlands than St. Paul Island. Common lichen species within the photograph area are *Alectoria nigricans*, *A. ochroleuca*, *Cetraria ericetorum*, *Cladina mitis*, *C. rangiferina*, *C. stellaris*, *Cladonia amau-rocrea*, *C. borealis*, *C. fimbriata*, *C. gracilis*, *Flavocetraria cucullata*, *F. nivalis*, *Lobaria linita*, *Parmelia omphalodes*, *Peltigera aphthosa*, *P. britannica*, *P. membranacea*, *P. scabrosa*, *Pertusaria alaskensis*, *Pseudephebe pubescens*, *Stereocaulon intermedium*, *Thamnolia vermicularis*, *Umbilicaria cylindrica*, *U. polyphylla*, and *Xanthoria elegans*.

*wardsii*, *Geum rossii*, *Papaver radicatum*, *Pedicularis langsdorffii*, *P. lanata*, *Potentilla villosa*, and *Silene acaulis*. Grassy banks and upland meadows are frequent, particularly near the sea. Some conspicuous species from these areas are *Pedicularis verticillata*, *Ranunculus eschscholtzii*, *R. sulphureus*, and *Valeriana capitata*. On St. Paul Island, there are few wetland species and only one true bog; *Sphagnum* is rare. Sandy shores and dunes are extensive and are characterized by meadow species such as *Elymus mollis*, *Honckenya peploides*, and *Lathyrus maritimus*.

Frequent cyclonic storms crossing the Bering Sea dominate the weather pattern (National Climatic Data Center 1986). The climate is maritime with considerable wind and cool, humid, and cloudy conditions. Mean annual temperature for St. Paul is 3.7°C and mean annual precipitation, 590 mm (Leslie 1989). A single year's data from St. Matthew Island recorded by the U.S. Army during the period September 1943–August 1944 (Klein 1959) showed a mean annual temperature of 3.2°C and total annual precipitation, 389 mm. Using an ecoclimatic-phytogeographical system, Tuhkanen (1984) included the study area in the hemiarctic subzone, hyperoceanic ( $O_2$ ) sector, and humid (h) province. Others place the area in the Low Arctic (Bliss & Matveyana 1991; Knapp 1965).

Volcanic rocks of Quaternary age underlie the study area (Beikman 1980). Major rock constituents are andesite and basalt lava flows, lahar deposits, sills, and plugs. Surficial deposits of both islands contain high percentages of volcanic rock particles, ash, and pumice flanking peaks of Quaternary and Tertiary age (Karlstrom et al. 1964). St. Matthew Island is underlain almost entirely of calc-alkaline volcanic rocks of Late Cretaceous and earliest Tertiary age (Patton et al. 1975).

The dominant soils of St. Matthew Island are Pergelic Cryaquolls and Pergelic Cryoborolls; these Mollisols have a mollic epipedon but no underlying horizon is dominated by ash material (Rieger et al. 1979). Other soils include Histic Pergelic Cryaquepts, Pergelic Cryofibrists, Pergelic Cryaquepts, and Pergelic Cryorthents. In contrast, the dominant soils of St. Paul Island are Typic Cryandepts, a type of Inceptisol formed in volcanic ash. Lithic Cryandepts are a minor type.

#### METHODS

Field studies were done during July, 1997 with collections from 25 localities. A total of 528 specimens were collected. All collections were made by the first, second, and fourth authors (SST, SLT, & WBS) and the collection

numbers are theirs. The third author (JWT) made all determinations. Voucher specimens are deposited in the University of Wisconsin Herbarium (wis). Nomenclature follows Esslinger and Egan (1995) with Internet updates, Esslinger (1998).

The primary purpose of our work on St. Matthew Island was to collect lichen and moss samples for elemental analysis in relation to air quality. Additionally, collections of macro- and microlichens were made to develop a baseline list of taxa as we traveled on foot to randomly selected sample sites. An attempt was made to include a representative spectrum of habitat types over complex topographic gradients. Our primary purpose on St. Paul Island differed from St. Matthew Island in that we focussed on the macrolichens because of their value to reindeer.

The major collection sites are shown in Figure 1 and listed below. The island name is followed by general location, latitude and longitude measured with hand-held Global Positioning System (GPS), elevational range, and collection date. For the habitats, we have simplified more explicit data presented on the labels in interests of saving space. Minor variations of location that help to explain differences in habitat are indicated as Arabic numerals.

#### ST. PAUL ISLAND:

- A.—East of Salt Lagoon, 57°08.0' N, 170°16.0' W, 30–45 m, 11 July 1997.
- B.—1.—Telegraph Hill, 57°08.8' N, 170°16.2' W, 91 m, 11 July 1997; 2.—South of Telegraph Hill at south end of pond, 57°08.4' N, 170°16.2' W, 30 m, 12 July 1997.
- C.—West side of Salt Lagoon, 57°08.2' N, 170°16.9' W, 30 m, 11 July 1997.
- D.—1.—Rock outcrop 0.5 km northeast of Telegraph Hill, 57°09.3' N, 170°15.5' W, 91 m, 12 July 1997; 2.—Talus slope 0.5 km northeast of Telegraph Hill, 57°09.5' N, 170°15.8' W, 91 m, 12 July 1997.
- E.—Tor like outcrop 1 km NW of Zapadni-Tolstoi Rookery, 57°09.5' N, 170°18.8' W, 30 m, 13 July 1997.
- F.—Bogoslof Hill, 57°10.7' N, 170°17.7' W, 152 m, 13 July 1997.
- G.—Polovina Hill, 57°11.0' N, 170°11.2' W, 61–91 m, 13 July 1997.
- H.—1.—Rush Hill, 57°11.1' N, 170°24.2' W, 122 m, 14 July 1997; 2.—0.5 km E of Rush Hill, 57°11.0' N, 170°23.7' W, 46 m, 14 July 1997; 3.—0.5 km SE of Rush Hill, 57°10.5' N, 170°21.8' W, 30 m, 14 July 1997.
- I.—1.—Cone Hill area, cave caldera, 57°10.3' N, 170°22.5' W, 122 m, 15 July 1997; 2.—Cone Hill area, cave caldera, 57°10.2' N, 170°22.7' W, 122 m, 15 July 1997.

#### ST. MATTHEW ISLAND:

- J.—1.—Coastal tundra 1.5 km NNW of Bull Seal Point, 60°33.1' N, 172°55.6' W, 12 m, 18 July 1997; 2.—Coastal logs 1.5 km NNW of Bull Seal Point, 60°33.1' N, 172°55.6' W, 12 m, 19 July 1997; 3.—Bird cliffs 1.5 km NW of Bull Seal Point, 60°33.1' N, 172°55.6' W, 3 m, 22 July 1997.
- K.—1.5 km NW of Bull Seal Point, 60°33.6' N, 172°56.4' W, 12–30 m, 19 July 1997.
- L.—1.—Talus slope area 1 km W of Bull Seal Point, 60°33.4' N, 172°56.8' W, 91 m, 19 July 1997; 2.—Coastal bluffs and talus slope area, Bull Seal Point, 60°33.0' N, 172°55.0' W, 2–70 m, 24 July 1997.
- M.—Fen area 1 km W of Bull Seal Point, 60°33.6' N, 172°56.9' W, 30 m, 19 July 1997.
- N.—2 km WNW of Bull Seal Point, 60°33.4' N, 172°56.0' W, 30 m, 20 July 1997.

TABLE 1. Geographic distribution patterns of lichens of St. Matthew (SM) and St. Paul (SP) Islands, Alaska. Values indicate the presence of each taxon occurring within each category; many are combinations of these. Percentage values are in parentheses. Key: A = arctic-alpine; B = boreal; C = coastal; M = amphi-Beringian; W = widespread; U = unclear; n = total number of lichens. Many lichens fall into more than one distribution pattern.

	A	B	C	M	W	U
SM (n = 148)	125 (83.9)	74 (49.7)	18 (12.1)	9 (6.0)	41 (27.5)	5 (3.4)
SP (n = 132)	98 (74.2)	66 (50.0)	20 (15.2)	7 (5.3)	36 (27.3)	11 (8.3)

O.—Sarichef Strait area, 60°34.5' N, 172°59.4' W, 30 m, 21 July 1997.

P.—1.—Hill 600 above Bull Seal Point, 60°32.8' N, 172°55.5' W, 152 m, 22 July 1997; 2.—Coastal cliffs at Bull Seal Point, 60°32.8' N, 172°55.5' W, 152 m, 22 July 1997.

Q.—Mountain 1475, Glory of Russia Cape area, 60°34.9' N, 172°55.8' W, 61–273 m, 23 July 1997.

World distribution patterns are assigned to each taxon using the following geographic categories (many have combinations of these): A, arctic-alpine north of the latitudinal treeline south into the mountains of the east (Adirondak and White Mountains) and west (Rocky Mountain and Cascade Ranges) (Thomson 1984); B, boreal, latitudinal treeline to the southern limit of the closed coniferous forest with some species being common in the temperate regions; C, coastal, present in a strip along the maritime coast and reflecting a maritime climate; M, amphi-Beringian, western American Arctic and also in eastern Asia; W, widespread, present in many or most of the other categories; U, unclear distributions, either under study or too poorly known taxonomically to be confident of published maps. We assigned these phytogeographic categories based on Arup (1994), Dibben (1980), Geiser et al. (1994), Gould (1994), Goward et al. (1994), Jahns (1981), Søchting & Olech (1995), Talbot et al. (1991, 1992, 1997), and Thomson (1984, 1997).

#### LIST OF LICHENS

One hundred thirty-nine taxa of lichens were found on St. Matthew and St. Paul Islands in the Bering Sea. Of these, 96 are new reports for these Bering Sea islands, 76 are new reports for St. Matthew Island, 36 for St. Paul Island, and 15 are new to both St. Matthew and St. Paul Islands. The present results, together with the existing literature records of species not collected by us, total 207 taxa.

The distribution pattern for lichens of St. Matthew and St. Paul Islands are given in Table 1. The lichen diversity is characterized by wide-ranging arctic-alpine and boreal species with a moderately well-represented coastal element. Amphi-Beringian species form a minor component. On St. Matthew Island, which is more northerly and with greater topographic relief than St. Paul Island, the percentage of arctic-alpine species is about 10% higher.

Taxa are ordered alphabetically; bold font indi-

cates taxa in our collection and normal font indicates taxa collected by previous workers. A single asterisk (\*) indicates that the taxon is the first known report from St. Matthew Island, double asterisks (\*\*) indicate the first known report from St. Paul Island, and triple asterisks (\*\*\*) indicate the first known reports from St. Matthew and St. Paul Islands. Taxa collected by previous workers are followed by symbols for the name of the island, SM = St. Matthew and SP = St. Paul, and the citation. Synonymy is given in cases where the taxon name has changed from the original report. The name of each taxon collected in the present study followed by symbols for island names; these are followed by collection site letter (A-Q) which is in turn succeeded by specimen number. This sequence is followed by substrate, habitat information, phytogeographic distribution class, and when applicable, citation of previously recorded species.

#### DISTRIBUTION PATTERNS

A low proportion of the species on the two islands show a strictly amphi-Beringian distribution

(6% and 5.3%). Although both islands have undergone severe overgrazing, the species of this distribution pattern should not have undergone greater selection for elimination than species of other distribution patterns. Amphi-Beringian distribution for other coastal areas within western Alaska are similarly low, Adak Island (7.8%, Talbot et al. 1997), Attu Island (5.2%, Talbot et al. 1991), Izembek National Wildlife Refuge (6.0%, Talbot et al. 2000), and Tuxedni Wilderness Area (4.1%, Talbot et al. 1992).

Our collection efforts were confined, on St. Matthew Island, to a limited portion of the island. Based on our overview of the island, however, it appears probable that our sample included most of the habitats available. The lichens of this island have attained great luxuriance since the disappearance of the reindeer, but there is no adequate baseline list available to indicate the lichen species that were present preceding the introduction of the herds. It is, therefore, impossible to assess the detailed influence of overgrazing on lichen diversity.

The situation is slightly improved for St. Paul Island, but the baseline is the one provided here, and the biodiversity undoubtedly has been affected by the current herds and their ancestors, particularly to their overgrazing during the winter season. We made a concentrated effort to sample sites where the animals could not graze (i.e., high on rock surfaces or deep among boulders), and obtained, in consequence, vouchers to document species otherwise in fragmentary condition in tundra, presumably through trampling and overgrazing.

It is of considerable interest that the proportionate representation of the various distribution patterns is extremely similar between the two islands. The richer representation of arctic-alpine species on St. Matthew Island (nearly 84%) can be attributed, in large part, to its more northern position as well as to its greater habitat diversity than that on St. Paul Island.

We must emphasize, however, that our time available for exploratory sampling on these islands was extremely limited, and that further taxa can be expected to be present. On St. Paul Island, we were unable to sample maritime sites through the presence there of fur seal colonies. On St. Matthew Island we were able to sample maritime sites.

#### ACKNOWLEDGMENTS

Our thanks to the Air Quality Branch, Division of Refugees, U.S. Fish and Wildlife Service, Denver, for funding support. We are grateful to the crew of the M/V Tiglax for safe passage from St. Paul to St. Matthew islands and return; David Cormany, National Marine Fisheries Service, for lodging on St. Paul; Victor Mercurief, TDX Corporation, for permission to collect lichens on St. Paul Is-

land; and two anonymous reviewers. Special thanks are given to John G. Brewer for map design and production.
